1. Project Structure

1.1 Phase descriptions

The project will be divided in 7 phases plus an exploration phase. The purpose of each of them will be as follows.

1.1.1 Phase 0: Exploration

Investigation of available technologies, team organization and creation of a basic framework of rules for the competition.

1.1.2 Phase 1: Concept of Operations (ConOps) and System Requirements

Further investigations on the technologies to be used and development of documentation detailing system requirements, as well as the user description and summary of the needs, goals, and characteristics of the system's user community.

1.1.3 Phase 2: System High-Level Design

The hardware and digital tool set to be used, as well as the basic structure of the programming will be decided.

1.1.4 Phase 3: System Detail Design and Modeling

Further details about the programming will be defined. The exact hardware to be used will be decided. Appropriate models for simulation will be created and used based on the available data for the chosen hardware.

1.1.5 Phase 4: System Implementation

The drone or its parts will be acquired and assembled if necessary. The necessary code will be created and implemented.

1.1.6 Phase 5: System Testing

Correct functioning of the drone will be tested from the lowest level (regulation of propellers, basic movement, etc) to the highest (AI and ML).

1.1.7 Phase 6: Competition

This phase includes both the joint effort between teams to set up everything necessary for the competition as well as the competition itself.

1.1.8 Phase 7: Retirement

Retirement or disposal of non-reusable materials used in the circuit through the appropriate recycling

1.2 Gantt Diagram

PHASE	START	END
0: Exploration	12-sep	23-oct
1: Concept of Operations (ConOps) and System Requirements	26-sep	11-dic
2: System High-Level Design	07-nov	23-dic
3: System Detail Design and Modeling	05-dic	29-ene
4: System Implementation	30-ene	02-abr
5: System Testing	27-feb	21-may
6: Competition	01-may	04-jun
7: Retirement	05-jun	18-jun

2. Engineering Process Control

The purpose of this section is to describe the activities and plans that will act as controls on the project's systems engineering activities. This list of required products will control the activities of the team performing each activity and will control the satisfactory completion of the activity. These plans should be prepared and sharpened when they are clearly needed. Also, other plans might be included when new tasks are undergoing.

2.1 Task Inputs

Every task should be performed according to the standards applying from the following ones:

- · ISO/IEC/IEEE Std 15288:2015 Systems Engineering Life-Cycle Processes.
- · ISO/IEC/IEEE Std 24748-2:2018 Guidelines for Application of 15288.
- · ISO/IEC/IEEE Std 15289:2017 Content of Information Items.
- · ISO/IEC/IEEE Std 29148:2018 Requirements engineering.
- · OMG SysML Specification v 1.6.
- · ISO-IEC Std 14882:2020 Programming languages C++.
- · ISO/IEC 9899:2011 Programming languages C.
- IEEE 1003.1 POSIX System API Specification.

2.2 Task Deliverables

Every undertaken task should include a report explaining the process followed and its main results. Moreover, each task will have its specific deliverables such as software or hardware produced.

2.3 Task Decision Gates

A list of critical activities that must be satisfactorily completed before a task is considered achieved should be elaborated before start working on the task. Concretely, on the technical side this means:

· Assess that the correct technical metrics were define for the project.

- Assess if the correct technical process was used to carry out the work for the phase.
- · Assess the difference between the expected results and the actual results.

On the project management side, this includes:

- · Assess the cost for collecting the technical metrics.
- · Assess the cost for using the process to carry out the work.
- Assess the difference between the planned baseline cost/schedule and the actual cost/schedule.

2.4 Reviews and Meetings

Each specific team responsible of performing each task will meet to coordinate the different subtasks and also, meet with different teams to align objectives and avoid repetitions. Meetings will be either face-to-face or remote, when necessary, through applications like Microsoft Teams or Zoom.

2.5 Software Development Plan

This plan describes the organization structure, facilities, tools, and processes to be used to produce the project's software. GitHub will be the main platform to develop software tasks, it will be used for both management and communication between different software parts. Also, more platforms could be included for more specific purposes. Software produced will be as simple as possible with a description of every step followed so that anyone can easily understand and modify the code produced. As an example, every number in the code should be named as a variable and include the variable definition.

2.6 Hardware Development Plan

Describes the organization structure, facilities, tools, and processes to be used to produce the project's hardware. Once the drone to be used is defined, hardware development plan will get elaborated. Different alternatives are being studied like buying an existing drone and furnishing it with the necessary tools or buying different components and building a drone from scratch.

2.7 Verification Plan

Its goal is to prove that the system meets the requirements and matches the design. Every deliverable must follow the corporate identity manual, and results obtained match the expectations.

2.8 Installation plan

Describes the sequence in which the parts of the system are installed. Once the different parts, both hardware and software, are defined and developed, an installation plan should be completed to avoid step-backs.

2.9 Configuration Management Plan

Describes the development team's approach and methods to manage the configuration of the system's products and processes. It also describes the change control procedures and management of the system's baselines as they evolve. As a complex project is being approached, it is expected that changes in the system's baselines must be made. Therefore, each task must be clearly defined step by step so that changes can be easily performed.

2.10 Risk management plan

It seeks to understand and avoid the potential cost, schedule, and performance risks to a project. It takes a proactive and well-planned role in anticipating problems and responding to them if they occur. The only certainty is that, in at least some small way, things will not go as planned. Risk management anticipates and controls these risks. Each stage will have its potential risks, so before performing them every step should be analyzed to establish the potential risks and try to minimize them. For example, before buying a drone, all alternatives should be taken into consideration because if an expensive drone is bought and it does not work appropriately, the budget limit will be exceeded.

3. Configuration Management Plan

This section explains repository and documentation rules. It will set the guidelines for everybody when they need to create code, a new document or update either of the two.

3.1 Repository Rules

Hell-ix as company has to follow some rules in terms of typology and way of working. This rules will increase the efficiency of our software engineers to develop the main program which will govern the drone. First of all, we have to develop the rules related with the name of the files on the repository:

- Name of the files has to be easy to understand by every participant of the group.
- Name of the files will be written without spaces and using the first letter of each word capitalized in order to distinguish all the part of the name.
 An example of name can be: "NameOfTheFile"

In a repository it is very important to have a correct version control in order to know exactly which changes have been done on the file. So to solve this problem software department will use a change log to print all the notable changes done on that version. This file could be useful for all the persons which are involved on the project to understand changes and solved it if there is a problem on the future. The structure of this file will be the following:

[Version] - yyyy-mm-dd

Notes regarding the file's version.

Added

New functionalities developed on this version, summarized as much as possible.

Changed

Notable changes done on this version which can be important on future versions.

Another important question to solve on this document is how to name the new versions of the main repository. To make a good version control it is compulsory to use "Tags" on the repository which can separate the different version of the project. In order to make a tag on a repository has to be done inserting on the command line the following commands:

git tag -a vX.X -m 'Version X.X'

The version control will be done by the use of 3 numbers: X.Y.Z which each

one has a different meaning:

- The first (X) is known as major version and it indicates the main software version. This number has to be changed when there is a stable version of software. Example: 1.0.0
- The second (Y) is known as minor version and it indicates new functionalities on the main version. Example: 1.2.0
- The third (Z) is known as revision and it indicates if it has done a revision of the code. Example: 1.2.3

All this numbers follow a progressive order increasing one unit on the number when there is a remarkable change on the code.

An important point of this document is how programmers will work simultaneously. This problem will be solve making a branch of the main repository. A branch is a copy of the repository in which you can work without modify the main code. Once all the changes has been developed, programmer has to merge this branch to the main code. To do this process they have to use the following commands:

git branch -a 'BranchName'

git merge 'BranchName'

In conclusion, this rules will improve work capacity of developers which are involved on the project. Also, it will avoid problems of overlapping work which can generate bad atmosphere over the team.

3.2 Documentation Rules

In this project, as in any other, the documentation has to follow some guidelines both in the way of doing it and in its nomenclature. Doing these two things in an orderly manner is crucial to work efficiently in a team.

Corporate templates are already created and have to be used in every document or presentation. They have been made with the corporate colours, type of letter and with the logos of both Hell-ix and ETSII UPM.

3.2.1 Nomenclature

As explained in the Systems Engineering Management Plan, GitHub will be the platform used by every member of the team. Documents uploaded here will all be named in the same strict way: "NameOfTheDocument_Version_Date". Several rules have to be followed:

- Underscores can only be used to separate the name of the document from the version and the version from the date. They must not be used for anything else.
- The name of the document will be written without spaces and with the first letter of each word capitalized. If an acronym for the name exists, it will be used instead and be fully capitalized.
- Versions will start with "1.0" and will be increased as 1.1, 1.2,... if the document update is partial. When the update is significant the first number will increase. For example: the latest version is 1.3 and an important update is done. Then the document version will be 2.0.
- · The date will have the format Day-Month.

This document, for example will be named as "SEMP_2.0_20-11".

3.2.2 Version Control

Every document will include a table of updates at the beginning in which it will be specified when who and what was updated. It will look similar to this:

VERSION	AUTHOR	REVIEWED BY	UPDATE	DATE
1.0	Name of the author(s)	Name of the manager	New document	XX/XX/XXXX
1.1	Name of the author(s)	Name of the manager	Chapter X	XX/XX/XXXX
1.2	Name of the author(s)	Name of the manager	Chapter Y	XX/XX/XXXX
2.0	Name of the author(s)	Name of the manager	An important change in the document	XX/XX/XXXX

Figure 3.1: Version Table

Managers will be responsible for supervising the correct document naming as well as the contents of their working area. Every team member will be aware of what to update, fill the Version Table with that information and to follow the format and style of the document. In order to accomplish this goal, managers will have another function that is the document naming monitoring.

Every member of the team must know when the following delivery dates are and those members who have work to do on them have to be well organized to finish it at least one day before deadline. Thus, the manager has time to check and approve that work. Before the last day, feedback is important

between both parts, so the last day there are only a few details to check and not the whole document.

To conclude, managers will have to be aware of everything related to the work they lead. They have to be able to make decisions and to be a problem solver for the rest of the teammates. Either way, project manager will always have a great weight on the resolution.
